

The research program of the Center for Economic Studies produces a wide range of theoretical and empirical economic analyses that serve to improve the statistical programs of the U.S. Bureau of the Census. Many of these analyses take the form of research papers. The purpose of the Discussion Papers is to circulate intermediate and final results of this research among interested readers within and outside the Census Bureau. The opinions and conclusions expressed in the papers are those of the authors and do not necessarily represent those of the U.S. Bureau of the Census. All papers are screened to ensure that they do not disclose confidential information. Persons who wish to obtain a copy of the paper, submit comments about the paper, or obtain general information about the series should contact Sang V. Nguyen, Editor, Discussion Papers, Center for Economic Studies, Room 1587, FB 3, U.S. Bureau of the Census, Washington, DC 20233-6300, (301-763-2065).

**MEASURING THE TRADE BALANCE
IN ADVANCED TECHNOLOGY PRODUCTS**

by

Thomas Abbott, Robert McGuckin,
Paul Herrick, and Leroy Norfolk

CES 89-1 January 1989

Abstract

Existing procedures used to construct high technology trade statistics do not provide an accurate picture of international trade in these products because of the level of aggregation used in their construction. Many low technology products are included in published trade statistics for high technology industries. In order to provide policymakers with improved information on high technology trade, the Census Bureau now publishes monthly trade statistics on advanced technology products (ATP). This paper discusses the methodology used to define the Census Bureau ATP measure, and contrasts it with the existing procedures.

Measuring the Trade Balance in Advanced Technology Products¹

1. Introduction

Because of the dramatic decline in the United States Trade Balance since the early 1970's, many economists and policy makers have become increasingly concerned about the ability of U.S. manufacturers to compete with foreign producers. Initially concern was limited to a few basic industries such as shoes, clothing, and steel; but more recently foreign producers have been effectively competing with U.S. manufacturers in automobiles, electronics, and other consumer products. It now seems that foreign producers are even challenging the dominance of America in high technology industries. The most recent publication from the International Trade Administration shows that the U.S. Trade Balance in high technology industries fell from a \$24 billion surplus in 1982, to a \$2.6 billion deficit in 1986, before rebounding to a \$591 million surplus in 1987.

As part of the efforts of the U.S. Census Bureau to provide policy makers and other interested parties with the most complete and accurate information possible, we recently completed a review of the methodology and data used to construct trade statistics in

¹We wish to thank Don Adams, Lester Davis, Timothy Dunne, Jeffrey Lins, Jerry Kotwas, Charles Waite and Peter Zadrozny for helpful comments on earlier drafts. We also thank Jan Parks for excellent assistance in manuscript preparation. The views expressed here are our own and do not necessarily reflect those of the Census Bureau.

the area of high technology trade. Our findings suggest that the statistics presented by the International Trade Administration, although technically correct, do not provide an accurate picture of international trade in high or advanced technology products because of the level of aggregation used in their construction.

The ITA statistics are based on the Department of Commerce's DOC3 definition of high technology industries. The DOC3 definition requires that each product classified in a high tech industry be designated high tech. As a result, many products which would not individually be considered high tech are included in the statistics. After developing a disaggregate, product-based measure of international trade in Advanced Technology Products (ATP), we find that although the trade balance in these products did decline over the 1982-1987 period, the decline is much smaller (about \$5 billion) than reported by ITA (approximately \$24 billion).

This paper discusses the methodology used to define the ATP measure, contrasts it to the DOC3 measure, and provides a comparison of the resulting statistics. After discussing alternative approaches to identifying advanced technology products, Section 2 describes the advanced technologies in the classification. (Appendix A, provides definitions and examples of the products which embody these technologies. In addition, Appendix B, available on request, provides a comprehensive list of Advanced Technology Products by technology grouping.)

Having described the ATPs, Section 3 examines annual trade statistics for ATP products, in 1982, 1986, and 1987, and compares these statistics with equivalent ones based on the DOC3 measure. The differences between the two measures over the 1982-87 period stem from changes in the balance of trade of items included in the DOC3 measure but excluded by the Census ATP measure; i.e. the differences are due to changes in the trade balance of "low tech" products which are produced in "high tech" industries. This finding corroborates a principal argument for construction of the ATP measure, that the weakness of the DOC3 measure of high technology trade is the level of aggregation used in its construction. It also suggests that at the level of individual products the high technology sectors of the economy continue to enjoy a strong comparative advantage and are surprisingly healthy. Nonetheless, some areas of weakness are identified, such as low tech products in high tech industries. (Appendix C, supplements this material by providing a detailed listing of traded products included and excluded from the Advanced Technology definition for each DOC3 high tech commodity grouping. These Tables enable the reader to directly assess the Census classification.)

2. Defining Advanced Technology Trade

Current Definitions

The Census approach to defining advanced technology is very

different from the one commonly used. Most definitions of high or advanced technology are based on industry-level data and use indirect measures of the "technology incorporated in the product" to determine which industries are included. These indirect measures include the ratio of R&D expenditures to sales and the ratio of "scientific and engineering" employees to other employees.² Several problems exist in the implementation of these indirect measures of the technology embodied in a product.³

The first and most important problem is that these indirect approaches use aggregated industry-level data R&D measures to classify "high technology" products. As a result, it is assumed that all products within an industry are either high tech or low tech. Our analysis of the individual products shows that most industries produce a mixture of high and low tech products.⁴

² In addition to DOC3 which is based on R&D expenditures and described in detail in Davis (1982), BLS experimented with several measures based on employment, see R.W. Riche, E.E. Hecker and J.U. Burgan (1983).

³ The indirect measures also have conceptual difficulties. They beg the question of what is "high technology" by pushing the issue back to questions of what are R&D expenditures? or what are "scientific and engineering" employees and how should these factors be accounted for in assessing the determinants of current output?

⁴ For example, "Office and Computing Machines," Industry Group 357, is included in almost every definition of high technology. The products in this industry include scales, balances, cash registers, calculators, dictation records, adding machines, and computers. Clearly, not all of these products would be considered as embodying advanced or leading edge technologies.

Moreover, in some industries the proportion of high and low tech products traded changes dramatically over time.⁵ Thus a more disaggregated approach, such as the product by product examination used by Census, is needed to properly measure the trade flows in high technology goods.

A second problem with the indirect approach is that it does not make a distinction between the product and the process used to make the product.⁶ Research and development associated with more efficient production processes may not result in a better, or more advanced, product.⁷ For example, developments in petroleum refining have led to great reductions in the amount of "waste" or residual fuels. These new processes require sophisticated control equipment and larger numbers of engineers. As a result, the petroleum industry while not included in DOC3 has been included in

⁵ In Industry Group 357, mentioned in the previous footnote, the proportion of total imports that were high tech increased from 62 percent in 1982 to 85 percent in 1987.

⁶ The Census Bureau has begun a survey of manufacturing plants designed to ascertain the nature of the technologies used in the production process. The results of this survey will provide some less aggregated information on the use of high technology processes. Comparisons of these input-based classifications with the ATP measures are not possible at this time.

⁷ Technological advances which reduce production costs make U.S. output more competitive in world markets. Conceptually, however, the product is the same and the competitive effect is similar to finding a cheap new source of an input.

some definitions of high technology.⁸ But is gasoline a high tech product? There is no difference between gasoline obtained using the old process and gasoline obtained using the new process. It is the process, not the product, which is high tech.⁹

The inorganic chemicals industry (SIC 281) is perhaps a better illustration from the standpoint of the DOC3 definition. This industry is included in the DOC3 definition because it has a relatively high R&D to sales ratio; however, much of the research and development is focused on new production processes. As a result, low tech products such as sodium carbonate (commonly known as soda ash) are included in the DOC3 high technology trade balance--soda ash was the largest export from this industry with a total of \$232 million in exports in 1986.

To allow for the heterogeneity of individual products within an industry and to focus on the nature of the traded product rather than the production process, one must examine international trade at the product level rather than at the industry level. Unfortunately, at such a detailed level, input-based measures such as research and development expenditures are not available, nor are they likely to be available in the near future. As a result, in a

⁸ The BLS measure of high technology, which is based on the ratio of the number of scientific and engineering employees to the number of other employees, includes petroleum refining.

⁹ Some of the equipment needed in the new petroleum cracking processes is, however, considered to be high tech by Census analysts. Such equipment is classified under computer integrated manufacturing technology.

process described more fully below, a list of advanced technologies are used by Census Bureau analysts to identify individual ATP products.¹⁰

The Census Advanced Technology Products (ATP) Definition

It was decided that an examination of individual products to determine if they were high tech was the best way to overcome the problems inherent in the DOC3 definition. The first step in this process is the development of a list of technological fields commonly included under the heading of advanced or high technology products. In creating the list of high technology fields, a number of different sources were consulted. These included Fortune Magazine's "Special Report: The High Tech Race" (October 13, 1986), CorpTech's High Technology Classification System, and the 1987 report, "The Status of Emerging Technologies: An Economic/Technological Assessment to the Year 2000" prepared for former Deputy Secretary of Commerce Brown.

From these sources, ten Advanced Technology fields were chosen: Biotechnology, Life Sciences (Medical Science), Opto-Electronics, Computers and Telecommunications, Electronics, Computer Integrated Manufacturing, Materials Design, Aerospace, Weapons, and Nuclear. Within each of these fields, large numbers of products, processes, and breakthroughs can be considered to be "on the leading edge" of their field. Descriptions of these fields

¹⁰ The Bureau is also conducting a separate survey of high tech manufacturing processes.

and examples of specific applications or breakthroughs are provided in Appendix A. A complete list of the individual products which constitute the "Advanced Technology Products" within these fields is given in Appendix B.

Application of Leading Edge Technologies to Individual Products

We examined products which are traded internationally by the United States to see if significant amounts of any of the leading edge technologies were embodied in the product. If a product had significant amounts of one or more of these technologies, it was considered to be an ATP. If the product did not contain a significant amount of one of these technologies it was considered

"o t h e r . "

Although one would clearly like to make this definition more "precise" by placing a value on the contribution of the advanced technologies to the product, such quantitative standards are not practical. For this reason, analysts were instructed to use their knowledge and judgment to determine whether or not a particular product contained significant amounts of these technologies.¹¹

The Census method is not perfect. Although most people would agree that advanced technology products are those which

¹¹ The analysts involved in the project work with the foreign trade data on a day-by-day basis and are very knowledgeable about the individual products, who is manufacturing them, and how they are manufactured. Thus, it is reasonable to ask them the extent to which a product embodies new technology.

embody special knowledge, training, and technology, it is very difficult to establish clear cut rules for classifying individual products as "high tech" and "other." The Census procedure relies on the judgment of individual industry analysts to evaluate and determine if a product is high tech or not. This implies that another set of analysts, working with the same data, may identify a somewhat different list of advanced technology products.

Although these problems of classification are difficult, they should not be overdrawn. Decisions similar to those made in developing the list of ATP's are regularly made in the classification of economic activity and related Census Bureau activities.¹² Without such decisions, one could only work with aggregate data or with the universe of individual establishments.¹³

Thus, it is natural to apply this expertise to defining advanced technology by directly classifying products.

N o n e t h e l e s s ,

¹² The industry definitions used by others in their definition of "high tech" trade are themselves based on Census Bureau decisions as to the assignment of individual establishments and products.

¹³ Standard Industrial Classification (SIC) system industry and product definitions are continuously reviewed and updated to reflect changes in the economy, and analysts use subjective judgments to assign individual establishments and products to particular industries. This classification system has been accepted by data users as the way of classifying economic activity in the United States. Few question the existing industry boundaries or the Census Bureau's ability to assign individual establishments and products to those industries even though the system itself represents a compromise between "several principles" of classification (See Abbott and Andrews, 1988.)

t o minimize the impact of "subjective" decisions the Bureau adopted several procedures. First, the judgments of the analysts were reviewed by trade experts inside and outside the Census Bureau. The analysts were pushed to justify the inclusion or exclusion of individual products, and in some cases, changes were made. Such reviews are carried out on a regular basis so that new products can be incorporated in the list and products which become dated can be removed from the list.¹⁴ Second, detailed studies of the differences between the Census ATP measure and the DOC3 measure can be used as the basis for specific review of products. Third, data on the level of imports and exports of products included in either the Census ATP or the DOC3 definition of high technology has been made available to users. Thus, researchers can examine both measures at a detailed level and conduct sensitivity analysis to determine the effects of including or excluding specific products from either measure.

3.	<u>Comparing</u>	<u>ATP</u>	<u>and</u>	<u>DOC3</u>	<u>Measured</u>	<u>Trade</u>
B	a	l	a	n	c	e
S						

Figure 1 contrasts the ATP and the DOC3 measures of the high technology trade balance. (The ATP measure of high technology

¹⁴ It is important to keep in mind that technologies are not static. New inventions and products continuously replace old products as the leading edge of science and industry continuously advance into new areas. Thus any list of high technology products cannot be static but needs to be continuously revised.

trade is the upper line in the figure.) One striking feature is that while both measures are very close in 1982, they quickly diverge and by 1985 the difference between the two measures is approximately \$20 billion. From 1982 to 1985 the two measures move very differently. Both show a decline from 1982 to 1983, but the DOC3 measure shows a dramatic decline, approximately \$12 billion, while the ATP measure has a decline of only \$3 billion. From 1984 to 1985, the ATP measure shows an increase in the trade balance, the DOC3 measure shows continued decline. From 1985 to 1987 both measures show similar movements, although they are at very different levels. Both decline from 1985 to 1986, and then rebound from 1986 to 1987. The underlying data for this and subsequent Figures 3 - 5 are given in Table 1.

The Census ATP measure of high tech trade consists of the sum of Groups 1 and 2. The ITA DOC3 measure of high tech trade consists of the sum of Groups 1 and 3. Group 1 is those products which both definitions label as high tech. Group 2 consists of those products identified as high tech by Census which are outside

industries labeled high tech by ITA. Group 3 consists of those products labeled high tech by ITA and low tech by Census, i.e., low tech products in high tech industries.

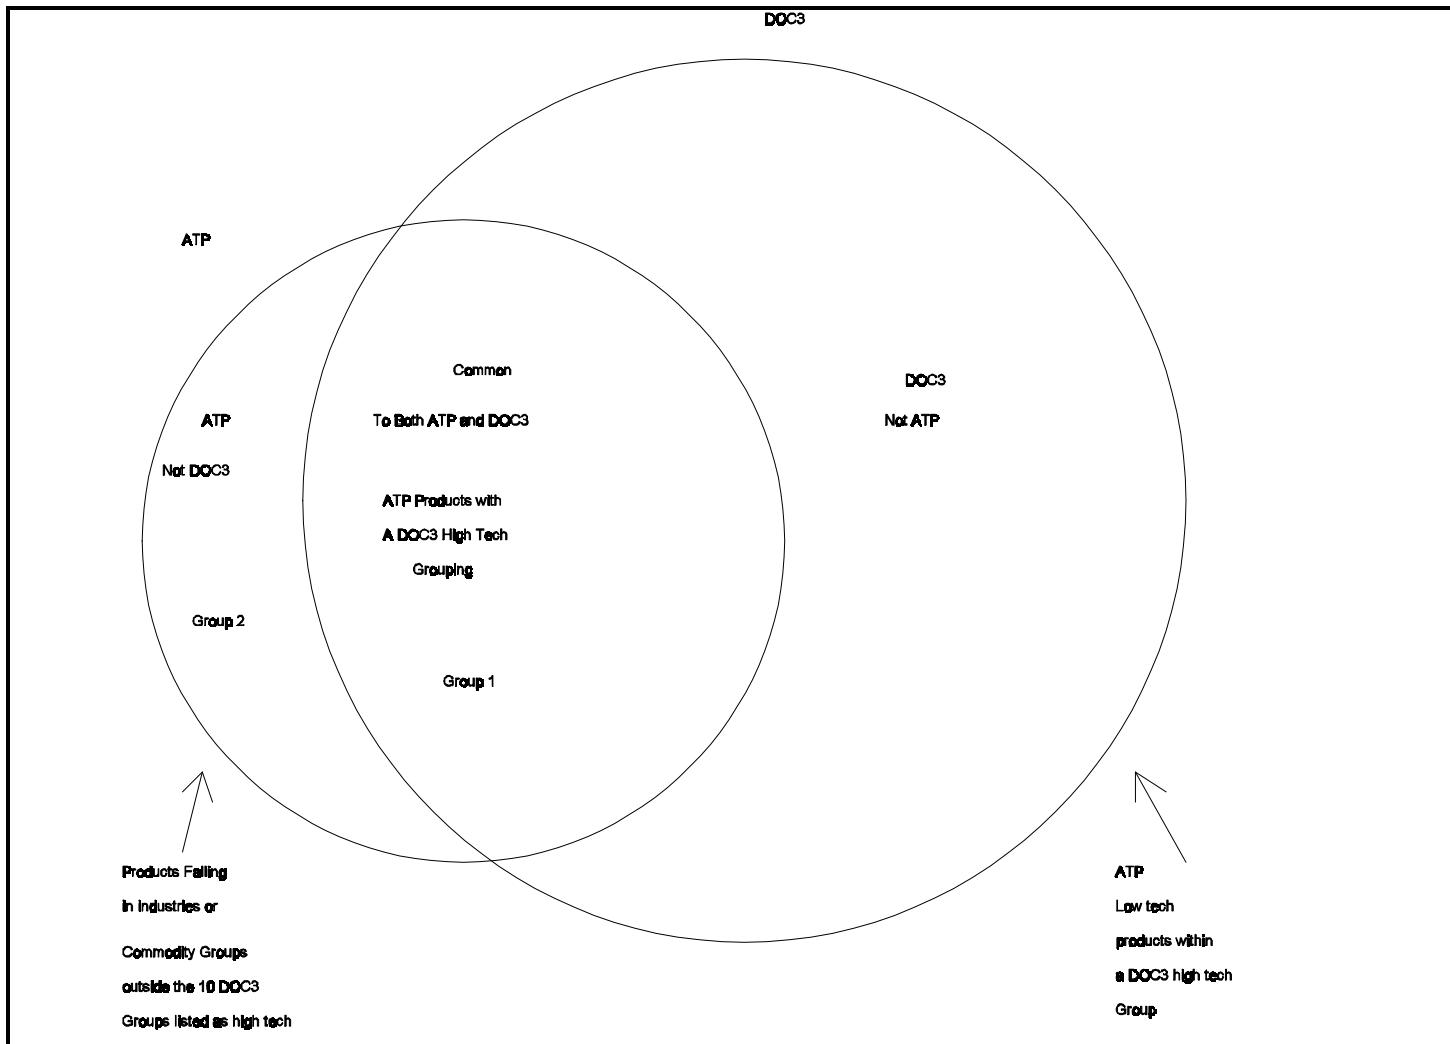

Figure 2

To examine the source of the differences between these two measures, it is useful to classify the traded products into three distinct groups. The three groups of products are 1) those products which are included in both the ATP and the DOC3 measure (the common component), 2) those products which are included in the ATP measure but excluded from the DOC3 measure, and 3) those products which are included in the DOC3 measure but excluded from the ATP measure. These groups are illustrated in Figure 2. Group 1 products include all those products which fall within one of the 10 DOC3 defined high tech industries which are also classified as ATP using the Census procedures. ATP products falling in industries outside the 10 industries defined by DOC3 comprise Group 2 products. Group 3 products represent low tech or non-ATP products which are classified in high tech industries defined by DOC3. It is this group of products which was initially cause for concern with the DOC3 measure and led to development of ATP. This group also provides most of the explanation for the difference between ATP and DOC3 trade statistics

Source of the Differences in Observed Trade Balances

Using these three groups of products, the movements over time in either ATP, DOC3 or the difference between the ATP and DOC3 measures can be examined. The time trend of each of these components is shown in Figure 3. The Group 1 products, those common to both the ATP and DOC3 measures, decline from roughly a \$23 billion surplus in 1982 to an \$18 billion surplus in 1984,

before rebounding to \$22 billion in 1985. From 1985 to 1986 there is a dramatic drop in the trade balance of these products, to a low of \$14 billion, before rising again to a \$17 billion surplus in 1987. The Group 2 products, those unique to the ATP measure, remain roughly flat at about \$2 billion surplus over the period. Thus the movement in the ATP measure is dominated by the movement of products which are common to both the ATP and the DOC3 measure. In contrast, the movement in DOC3 is dominated by the low tech Group 3 products unique to it. The trade balance of these products shows a sharp decline over the period. Starting at a \$1 billion surplus in 1982, Group 3 products fall to an \$18 billion dollar deficit in 1985 and then remain stable through 1987.

Thus, it is the Group 3 component which explains the differences (both absolute and overtime) between the ATP and DOC3 measured high tech trade balances. This means that the trade balance of "low tech" products (according to Census Bureau analysts) in "high tech" industries (according to ITA) is the primary difference in the two high technology measures. This verifies the initial concern about using industry-based measures. More importantly, the difference between the movements and levels of the Group 1 and Group 3 products provides *prima-facia* evidence that the distinction made by the Census Bureau analysts between high and low tech products reflects real differences in the products. If all of the products manufactured in high tech industries

ATP - DOC3 Differences

Balance of Trade

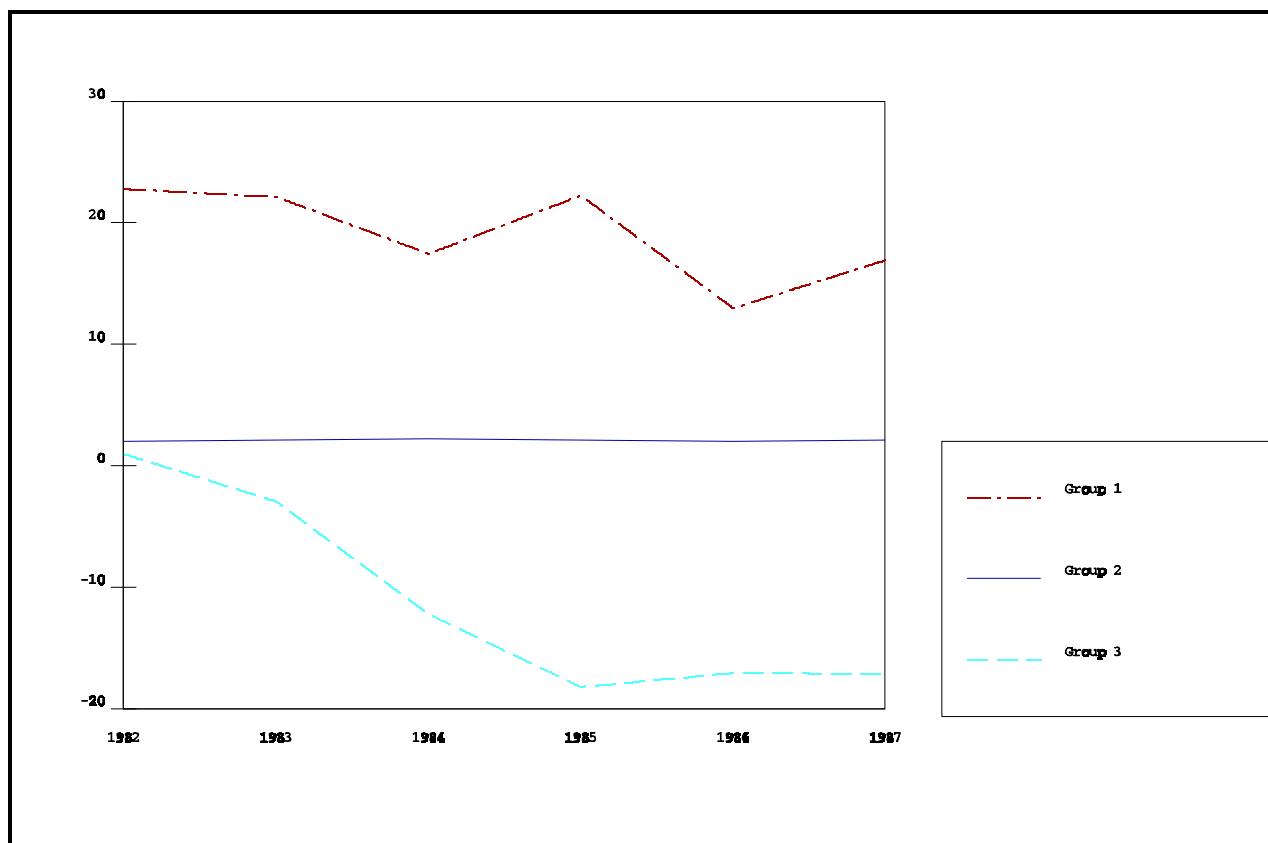

Figure 3

were in fact identical (as implicitly assumed in the DOC3 definition), then one would expect the trade patterns of Group 1 and Group 3 products to be very similar, which they are clearly not.

Differences in Imports Among the Groups

Figure 4 compares imports between the three groups. It shows that the Group 1 and Group 3 imports rise over the 1982 to 1987 period in a similar fashion. The Group 2 imports (those unique to the ATP measure) stay roughly flat at about \$1 billion dollars over the period. Thus, the dramatic increase in imports over the 1982-87 period, from \$34.5 billion to \$83.5 billion, was, roughly speaking, equally split between low tech and high tech products.

Differences in Exports Among the Groups

Figure 5 makes similar comparisons for exports. Over the 1982 to 1987 period the Group 1 exports, those common to both the ATP and DOC3 measure, rose fairly rapidly. Group 2 exports, those only included in the ATP measure, were small in magnitude and showed little change over the period. Thus, they moved very similarly to Group 2 imports. Figure 5 also shows Group 3 exports were essentially flat. Thus, exports of low tech products manufactured in high tech industries were stagnant over the 1982 - 1987 period. This contrasts with the rapid growth in such imports discussed above. This evidence is consistent with the interpretation that the United States experienced increased foreign

competition at the "low tech" end of these industries. In fact, Table 1 shows that, even though total exports rose over the period (by about \$25 billion) most of the increase (\$21 billion) was in the high tech grouping. This export stagnation in low tech products coupled with the rise in imports of these products in high tech industries is the primary explanation for the large fall in the DOC3 measure of high technology trade.

ATP - DOC3 Differences

Level of Imports

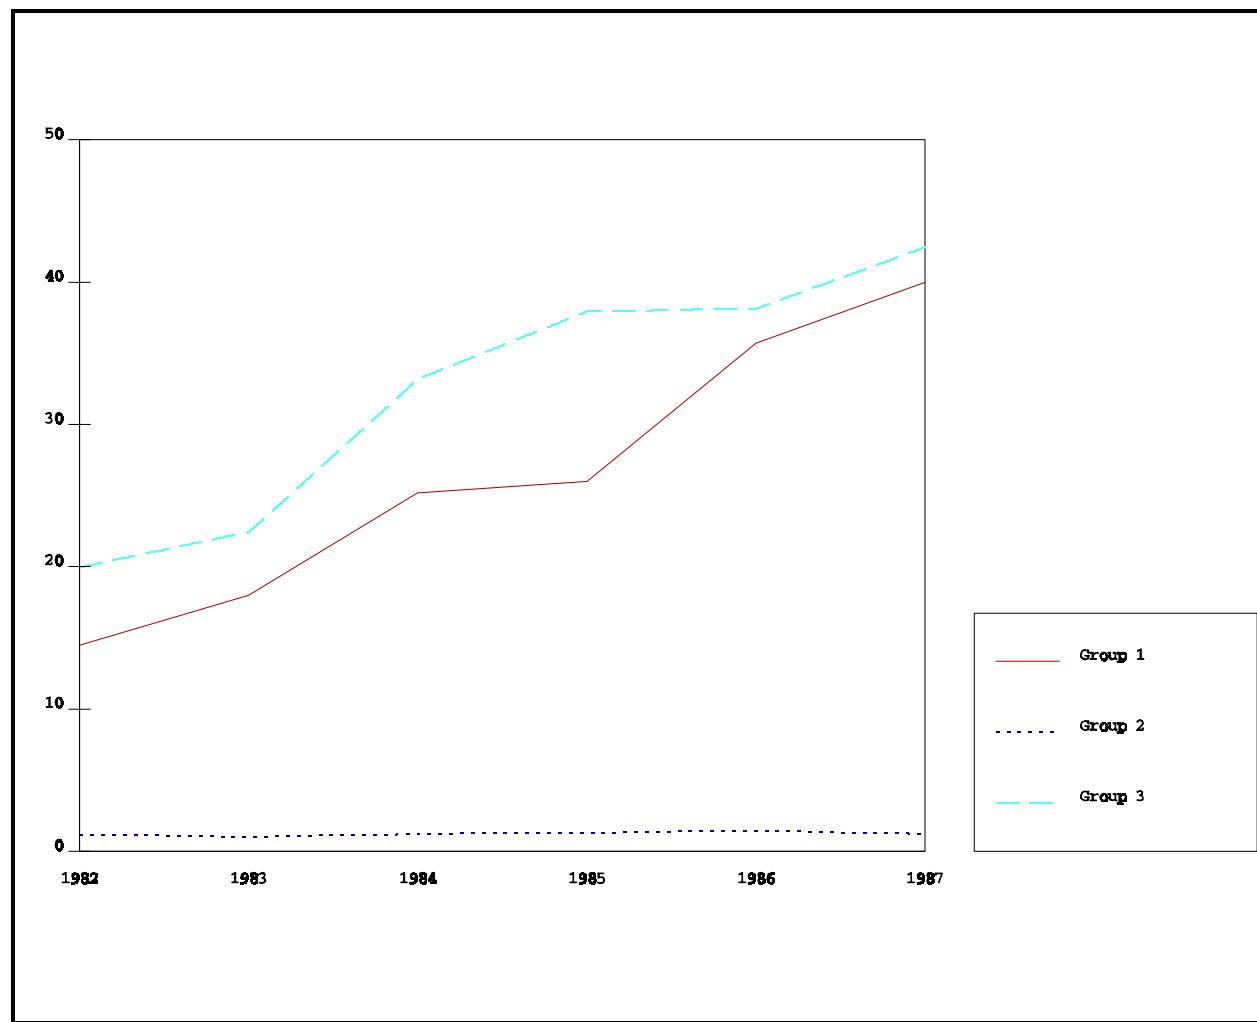

Figure 4

ATP - DOC3 Differences

Level of Exports

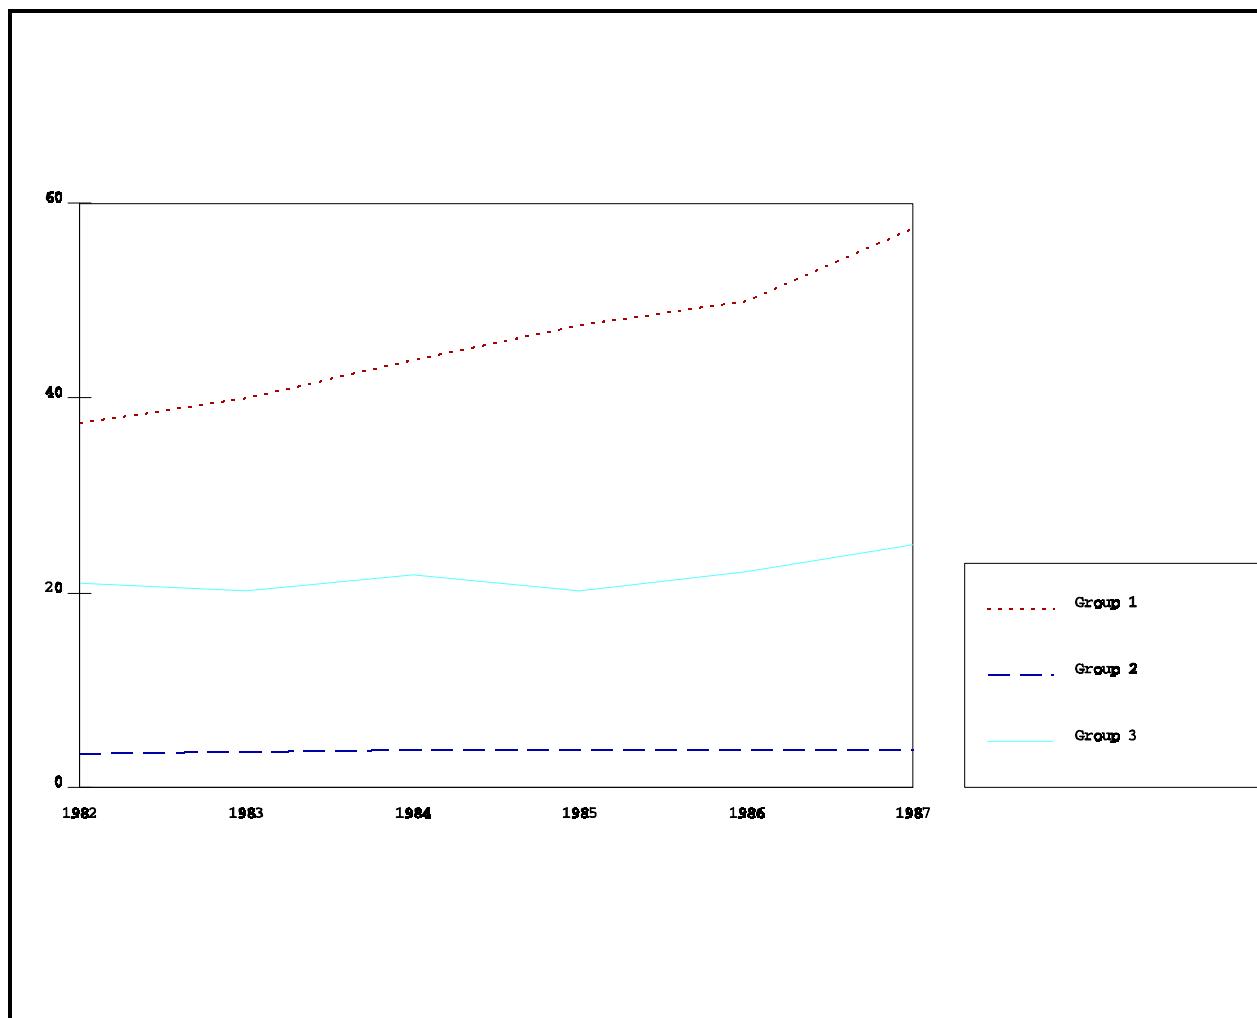

Figure 5

Distribution of ATP and DOC3 Differences by Industry

Figures 6 and 7 provide information on the distribution of the high- and low tech products across the 10 industries used to define high technology for the ITA report. The figures show the relative importance of each industry, in either exports or imports, as well as the portion of trade considered by Census Bureau analysts to be high or advanced technology products. For example, Figure 6 shows that Drugs and Medicine has approximately \$3.6 billion in Exports in 1987 composed of about \$.3 billion of high tech and \$3.3 billion of low tech products. As stressed throughout, not all products produced by an industry are the same. The ATP measure identifies only those products on the leading edge of new technologies while the DOC3 definition takes all of an industry's products as high tech.¹⁵

Figure 6 shows that a substantial proportion of the exports of Communications Equipment and Electronic Components is not considered high tech by Census Bureau analysts, and that this industry alone accounts for a difference of about \$6 billion dollars in exports as measured by ATP and DOC3. The Plastics and Resins industry accounts for another substantial difference in

¹⁵ For example, products in the Communications Equipment and Electronic Components industry which are not included in the ATP measure include, in order of importance for exports, printed circuit boards, sound recordings NSPF, television apparatus NSPF, and terminals and electrical splicers. The NSPF (Not Specifically Provided For) is a category which contains a mixture of products which could not be classified elsewhere.

measured exports because most of the products from this industry are not high tech even though the industry, as a whole, was a part of the DOC3 definition because of its high R&D to sales ratio. Other substantial differences occur in the Drugs and Medicines industry, the Industrial

Total 1987 Exports in DOC3 High Tech Industries

by ATP Low and High Tech Classification

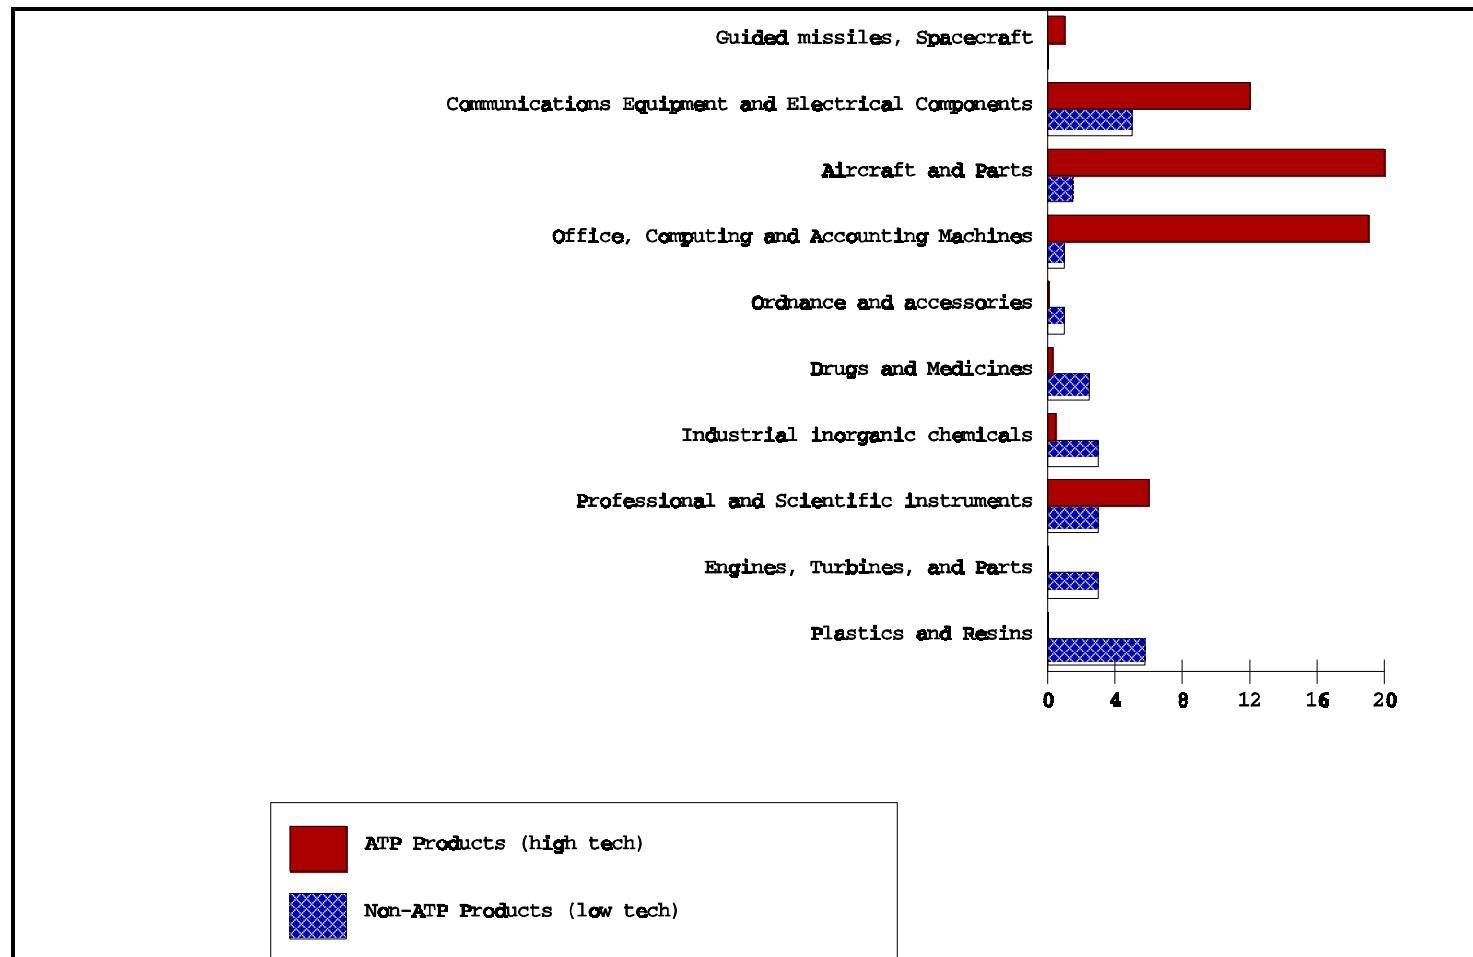

Figure 6

Total 1987 Imports in DOC3 High Tech Industries

by ATP Low and High Tech Classification

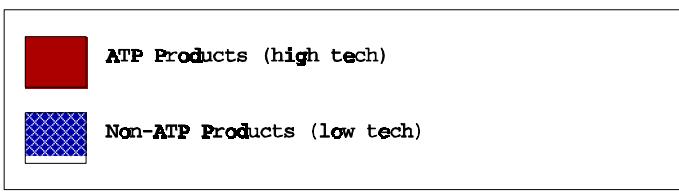

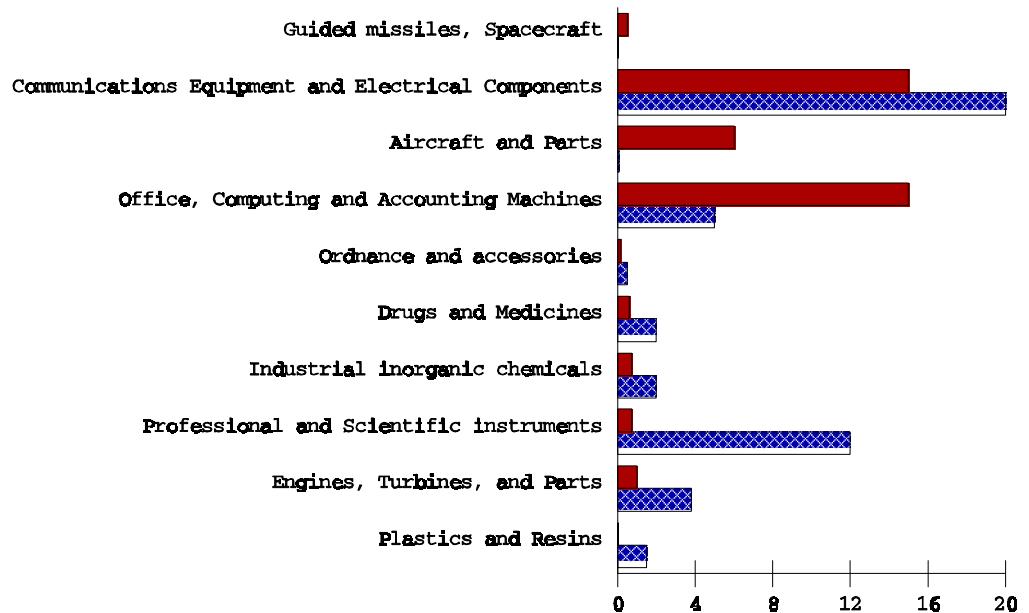

Figure 7

Inorganic Chemicals industry, the Professional and Scientific Instruments industry, and the Engines, Turbines, and Parts industry.

Turning to Figure 7 substantial differences in imports between the ATP and DOC3 definitions arise primarily in two industries, the Communications Equipment and Electronic Components industry and the Professional and Scientific Instruments industry. Both of these industries were of prime importance in the decrease in the trade surplus as measured by DOC3. The individual product data shows that there were significant increases in the importation of cheap foreign radios and tape players between 1982 and 1986 in the communications equipment and electronics components industry. These products were classified as low technology products by Census Bureau analysts but fell into the high technology grouping under the DOC3 definition. Similarly, in the Professional and Scientific Instruments industry, a major category of imports which were omitted from the ATP product list but included in DOC3, is watches. For the most part these imported watches are cheap, mass produced, electronic watches which are not on the leading edge of scientific instrumentation.

These observed differences in the classification of products across industries using the ATP and DOC3 definitions of high tech trade can be related directly to the earlier discussion regarding the weaknesses in the DOC3 approach. One major limitation with DOC3 was that it did not distinguish between

product and process development. Many industries with sophisticated process technology have high research and development expenditures and hence are included in the DOC3 measure; but because the product output is not advanced technology, they are not classified as high technology by Census Bureau analysts. Good examples of this are the Drugs and Medicines, Industrial Inorganic Chemicals, and Plastics and Resins industries. These industries are dominated by process rather than product development. They all show low proportions of total DOC3 imports and exports included in the Census ATP measure.

A second reason for differences between the industry R&D measure and the product based measure is the nature of the products produced versus the products traded. In some instances, an industry produces high tech products, and hence has high R&D expenditures, but exports few high tech products. This issue is greatest in areas of National Security interest where producers are strictly regulated in the products which they can export. The Ordnance and Accessories industry, and to some extent the Engines, Turbines, and Parts industry, have strong ties to products with military applications. In Ordnance and Accessories there were virtually no imports or exports of ATP products; and in Engines, Turbines, and Parts, ATP imports were well above exports. The DOC3 measure, being based on the R&D of the industry, fails to allow for regulations of this kind in constructing its measure of high technology trade because of the assumption that all products in the

industry have the same level of technology. In contrast the ATP measure which focuses directly on traded products enables careful consideration of the issue.

Advanced Technology Trade Balances

Having defined the advanced technology products, one can aggregate the level of trade across each of these products and obtain a measure of the aggregate imports, exports, and trade surplus in each ATP. Table 2 compares traded balances for each technology from 1982 to 1987.

For 1982, almost half of the \$24.6 billion trade surplus was due to a surplus in the trade of Aerospace products (\$11.9 billion). The United States

Table 2: Advanced Technology Trade Balances by Technology
 (Millions of Dollars)

Technology	1982	1986	1987
Biotechnology	106	-54	-48
Life Sciences	2060	998	1129
Opto-Electronics	173	-515	-549
Computers and Telecommunications	6920	141	1037
Electronics	-1783	-2636	-3307
Computer Integrated Manufacturing	2114	1903	2240
Materials Design	1419	1717	2646
Aerospace	11908	12402	14914
Weapons	75	236	162
Nuclear	1554	1448	1201
	-----	-----	-----
	24547	15641	19425

also enjoyed a surplus of over \$6.9 billion in Computers and Telecommunication equipment. The only technological area where the United States was a net importer was in the area of Electronics, where there was a \$1.9 billion trade deficit.

By 1986, the trade surplus in advanced technology goods had fallen to \$15.6 billion although the Aerospace technology remained strong (\$12.4 billion). The United States suffered severely in the Computer and Telecommunications fields (where it just barely maintained a surplus) and in Electronics (where the deficit increased to \$2.6 billion). Small trade deficits were also observed in Biotechnology (\$5.4 million) and in Opto-Electronics (\$51.5 million) in 1986.

In 1987, the advanced technology trade rebounded to a surplus of \$19.4 billion. The increase in surplus was due, in part, to a resurgence in Aerospace, as well as increases in the trade surplus in Materials Design and Computer Integrated Manufacturing. The United States continued to have a significant trade surplus in the areas of Nuclear Technology, and in the Life Sciences (Medical) technologies. Small deficits remain in Biotechnology (\$48 million) and Opto-Electronics (\$54.9 million). The weakest technology was Electronics in which the deficit continued to expand (\$3.3 billion).

These results are consistent with the popular notion that the United States has been losing ground to foreign competitors in some of the high or advanced technology fields. They are not

consistent, however, with the general view that the United States is currently running a trade deficit in these areas; and moreover, there are clear signs that the United States continues to be a strong competitor in a number of important areas.

5. Conclusions

Not surprisingly, the basic conclusion of this paper is that the answer to the question of whether the United States has lost its comparative advantage in high technology goods depends on how you measure it. The paper refocuses attention on the question of what is meant by high or advanced technology goods. Do we mean goods produced in R&D intensive industries as is the basis for DOC3? Do we mean goods that embody new or leading edge technology as is done in constructing ATP? A third possibility could be goods which were produced using complicated or advanced technologies. As we have seen, these different approaches provide different measures. Most importantly, having arrived at a definition of high technology, the implementation of that definition is extremely important to the measure of trade in high technology goods. In constructing the ATP measure of international trade, the Census Bureau focuses on the technology embodied in the individual products and uses analysts familiar with the products to classify them as high tech or other. Until now policy makers have had to use aggregate industry statistics. This limited the range of policy options which could be evaluated. The Census Bureau's ATP

measure, and its underlying product level data, provide a wealth of detailed information about international competition at the product level. This level of detail should permit the development, implementation, and review of much more narrowly aimed policy actions than is possible with DOC3.

Finally our analysis of the advanced technology trade balance suggests that care should be taken before special programs to protect, promote, or stimulate high technology industries are undertaken. At the level of individual products, the high technology sectors of the economy are surprisingly healthy. However, we also find that for those products which are no longer on the leading edge of their technology, i.e. the low tech goods produced by the so-called high tech industries, there is significant international competition; but this is also true for many other industries as well. International competition appears to have increased in all sectors.

APPENDIX A

Advanced or High Technology Fields

The Census list of fields involving advanced or high technology is Biotechnology, Life Sciences (Medical), Opto-Electronics, Computer and Telecommunications, Electronics, Computer Integrated Manufacturing, Materials Design, Aerospace, Weapons, and Nuclear Technology. Within each of these fields, large numbers of products, processes, and breakthroughs can be considered to be "on the leading edge" of their field. Note also, that there is a great deal of overlap across these fields, as breakthroughs in one area typically have applications in other fields. More specific details including a list of products included and excluded from each technology field appear in Appendices B and C, available on request. Descriptions of each field follow.

Biotechnology:

Biotechnology covers recent developments in recombinant DNA research and genetic engineering. It is a new field, based on discoveries in the 1950's, and has only recently been applied to the production of goods. The most obvious examples of biotechnology products are drugs, enzymes, and other therapeutic items. The field has also yielded benefits in agricultural production. New genes have been developed which increase the immunity of plants to diseases and provide them resistance to various herbicides. New food products are being developed with this technology. In

addition, new applications of microorganisms for the production of drugs and other complex molecules holds promise for both new products and processes.

Life Sciences (Medical Science):

This field encompasses the application of scientific advances to medical sciences. Recent advances such as nuclear resonance imaging, echocardio-graphs, and total-patient monitoring systems are examples of products developed from recent technological advances in the field. Recent increase in the strength of materials and reductions in their weight have led to improved internally implemented fixation devices and prostheses. Novel chemistry coupled with new production techniques for the manufacture of drugs has lead to many new products for the control or eradication of diseases. There is considerable overlap between products containing life sciences and biotechnology technologies.

Opto-Electronics:

Opto-Electronics is generally defined as the expanded development and application of the laser. However, recent advances in the field also include photoelectric cells and diodes, photographic and other imaging equipment, and fiber-optic cables. Many of the products incorporating opto-electronics technology have military application and have trade restrictions placed on them. There is considerable overlap between products in this field and those containing advanced telecommunications and materials design technologies.

Computer and Telecommunications:

This area is intended to cover technological advances affecting both computer and telecommunications hardware products. The distinction between computer and telecommunications products is becoming more difficult to make and has resulted in these areas being combined. The primary advances in this field are on developing hardware which can more quickly process information.

The area of computer products includes new designs which expand the field of applications, the development of increased data storage capacity, and, the development of smaller, more efficient peripherals. Important breakthroughs are expected in the areas of artificial intelligence and parallel processing, and new developments in opto-electronics may lead to dramatic gains in computer processing by allowing computers to operate by using photons rather than electrons.

In the area of telecommunications, hardware has been developed which can simultaneously transmit audio and video signals. In addition, advances in digital signal processing are being incorporated in improved signals switching systems. Breakthroughs in materials design technology have made many of these new products possible.

Electronics:

The miniaturization of electronic components is the most important recent technological advance in the field of electronics. Extensive development occurring in the design of integrated

circuits has improved their performance and capacity and, at the same time, reduced the size of the circuits. Although most discussions focus on integrated circuits, the field has also made significant strides in the design of discrete semiconductors such as transistors and diodes, as well as new developments in surface mounting of electronic components such as capacitors and resistors. Again, there is considerable overlap with computer and telecommunications technology.

Computer Integrated Manufacturing:

This field includes developments in robotics and numerically-controlled (NC) machine tools. These products have had a significant impact on industrial automation. Robots and NC machine tools perform increasingly sophisticated operations through developments in sensory and visual capabilities of machines. With these breakthroughs the manufacturing processes have increased in flexibility and require less human intervention to operate and maintain production machinery. Robots and NC machine tools are also used in sterile work environments. Many of the new automation technologies are made possible because of breakthroughs in the application and development of faster and smaller computers. So again, there is some overlap in the classification of these technologies.

Materials Design:

Materials design includes the newest methods of production for products which already exist in the market as well as the

development of new products. Recent examples of the technological advancements include high temperature superconductors, advanced polymers which expand the areas of plastic use, and new ultra clear glass that allows fiber optic cable to be used for long distance communication. The materials in this category often facilitate the development and application of other advanced technologies. For example, advances in preparation and design of ultra-thin films make possible smaller and faster computer components and advanced polymers strengthened with carbon fibers are used in the latest weapons, aircraft, and products of nuclear technology.

Aerospace:

Technological developments in this field include advances which allow planes to fly further, faster, and higher, to use less fuel, and to have quieter engines. Many of the advances have been adapted to military applications, such as vertical take-off aircraft and aircraft which require shorter distances for takeoff and landings. Also covered by this area are aircraft and rocket propulsion systems developed to provide greater efficiency and power. Many of these developments are the result of breakthroughs in other fields particularly the materials design technologies.

Weapons:

This field covers all advanced methods used for the development, guidance, and control of weapons intended for national or personal protection and deterrence. Many of the developments in this area are the result of breakthroughs in computers and

telecommunication as well as aerospace technologies. Advanced detection of hostile forces and their nature are also included in the field. Products that extend the use of such weapons to unique situations, such as resistance to high temperatures, and high strength are also included. Here there is considerable overlap with materials design technology. Much of the advanced work in this field is secret and not directly known outside of the Department of Defense.

Nuclear Technology:

This field covers developments in nuclear power production and primary nuclear reactors. It includes newly designed reactor components which improve the safety and efficiency of nuclear power plants. It also includes developments in the creation and packaging of nuclear fuel, and the application of atom physics to medical and other areas of science.

APPENDIX B: ADVANCED TECHNOLOGY PRODUCTS LIST

IMPORT CODES BY TECHNOLOGY TYPE

BIOTECHNOLOGY

<u>ITEM CODE</u>	<u>SIC CODE</u>	<u>DESCRIPTION</u>
